Latest Download wmv.The present invention relates to a container for the collection of specimens for laboratory testing. More particularly, the present invention relates to a sample collection container for the collection of a specimen from a patient into a test tube. Specimens taken from patients have many uses. These uses include medical diagnostic tests to determine the presence of specific diseases. Specimens may be sent to medical laboratories for testing, e.g., bacterial cultures, tissue cultures, tissue smears, fluids such as blood, urine, tissue extracts or other diagnostic tests. To accomplish this task, a technician or phlebotomist may obtain a sample by a variety of techniques, including using a syringe, a needle, a lancet or by surgical procedure. Of course, the choice of technique is largely based on the type of specimen. Blood specimens are typically taken by venipuncture through the use of a syringe or other similar device. For example, blood samples are commonly taken from a patient during a routine physical examination or a routine check-up by a phlebotomist for use in medical diagnostic tests such as blood typing, blood chemistry, serological tests, hematological tests, immuno-chemistry tests, and so on. In particular, blood samples are usually drawn by venipuncture through the use of a sterile hypodermic syringe. Another technique for obtaining a specimen is through the use of an oblong container. For example, U.S. Pat. No. 4,998,587 to Tully discloses a sample collection assembly having a two piece disposable specimen collection assembly. The first collection assembly includes a rigid base having an opening and a first cover having an opening through which the specimen passes and is collected. The second collection assembly is a flexible bag into which the first collection assembly is inserted. When the user chooses to remove the first collection assembly from the flexible bag, a cutting mechanism disposed in the flexible bag cuts

The next steps in the development of human preimplantation embryos are the transition to a pluripotent blastocyst and further differentiation into an embryo and an extra-embryonic trophoblast. In this study, we have established, and used as a standard, a model that facilitates differentiation of human preimplantation embryos to a defined state of pluripotency. Blastocysts were cultured in chemically defined serum-free conditions from the two-cell stage to the blastocyst stage, whereupon they expressed genes characteristic of the preimplantation stages (the zygote and cleavage stages) as well as trophoblast differentiation (hCG) and early implantation (LOX). Our data 2d92ce491b
